Overview

Learn what aerial fiber optic cable is, its main types including ADSS, Figure 8 and OPGW, core features, installation benefits and practical applications.

Key Takeaways

Aerial optical cables are fiber-optic cables installed above ground, either self-supporting or attached to existing structures, while optical attached cables (OPAC) are specifically lashed, clipped, or wrapped onto host conductors along power lines.

Aerial Optical Cables

Aerial optical cables are suspended from poles, pylons, or buildings and are designed for outdoor deployment in telecommunications and data networks. They can be: All-Dielectric Self-Supporting (ADSS): These cables are strong enough to support themselves between structures without metal support, suitable for installation near power lines up to certain voltage ratings. Optical Ground Wire (OPGW): Combines grounding and fiber-optic communication in one cable, typically installed on high-voltage transmission lines.

Loose Tube or Ribbon Designs: Loose tube cables contain buffer tubes with multiple fibers, while ribbon cables allow high fiber density and mass-fusion splicing for faster installation and restoration. Aerial cables can be self-supporting or require a messenger wire for mechanical support. They are available in various fiber counts, sheathing types, and mechanical constructions depending on span length, environmental conditions, and network requirements.

Optical Attached Cables (OPAC)Optical attached cables are installed by attaching a fiber-optic cable to an existing host conductor, such as a power line. The attachment methods include: Wrapping: The cable is helically wrapped around the host conductor, the most common method worldwide. Clipping or Lashing: The cable is clipped or lashed to the host, though these methods are less common.

Installation typically uses specialized equipment that moves along the host conductor, wrapping or clipping the cable in place. For low-voltage lines, the wrapping machine can be hand-pulled, while high-voltage lines require motorized or radio-controlled units.

OPA

C systems are widely used for telecommunications along existing power infrastructure, providing a cost-effective way to deploy fiber without installing separate support structures. Monitoring and sensing: Some aerial cables are designed for temperature, vibration, or intrusion monitoring. Integration with power infrastructure: OPAC and OPGW cables allow utilities to combine communication and power transmission functions. In summary, aerial optical cables provide flexible deployment options for outdoor fiber networks, while optical attached cables leverage existing power line infrastructure for efficient fiber installation, with wrapping being the most common method globally.
