CWDM Coarse Wavelength Division Multiplexer Active

Overview

CWDM uses a multiplexer to divide the light wavelengths into different channels, each carrying a separate data stream.

Key Takeaways

CWDM is an optical networking technology that increases fiber capacity by transmitting multiple data streams over different wavelengths on a single fiber, using wider channel spacing for cost-effective, short-to-medium distance applications. What is CWDM? Coarse Wavelength Division Multiplexing (CWDM) is a type of Wavelength Division Multiplexing (WDM) that allows multiple independent optical signals to be transmitted simultaneously over a single fiber by assigning each signal a distinct wavelength of light.

CWD

M is called "coarse" because the spacing between channels is relatively wide, typically 20 nm, compared to Dense WDM (DWDM), which has much narrower spacing. This wider spacing simplifies the design of optical components and reduces costs.

How CWD

M WorksCWDM systems use a multiplexer (MUX) at the transmitter to combine multiple wavelengths onto a single fiber and a demultiplexer (DeMUX) at the receiver to separate them back into individual channels. Each wavelength carries a separate data stream, which can include a mix of SAN, WAN, voice, and video services.

CWD

M can support up to 18 wavelengths over a single fiber pair, with each wavelength operating independently without interference. The system is often deployed in a plug-and-play modular architecture, making it suitable for rapid deployment in enterprise and metropolitan networks. Wavelength Range and Channel SpacingCWDM typically operates in the 1270–1610 nm range of the optical spectrum.

The wide 20 nm spacing between channels allows for less precise temperature control and simpler transceiver designs, making CWDM more cost-effective than DWDM for shorter distances. OH-free silica fibers are recommended when using wavelengths that span the second and third transmission windows to minimize signal loss. ApplicationsCWDM is ideal for short-to-medium distance networks, such as: Enterprise networks requiring increased bandwidth without installing new fibers Metropolitan area networks (MANs) for connecting multiple sitesFiber-to-the-x (FTTx) deployments, including residential and business connections Backhaul for wireless systems, including cellular towers and WiFi hotspots It provides a dedicated optical channel for each user or service, allowing service providers to maximize the capacity of existing fiber infrastructure without expensive upgrades.

CWD

M vs DWDMThe main differences between CWDM and DWDM are: Channel spacing: CWDM uses 20 nm spacing, DWDM uses 0. 4–1. 6 nm spacing Number of channels: CWDM supports fewer channels (up to 18), DWDM can support 40–88 or more Distance and amplification: CWDM is suitable for shorter distances without optical amplification, while DWDM is optimized for long-haul networks with amplification Cost and complexity: CWDM is simpler and more cost-effective, DWDM requires precise wavelength control and more sophisticated components CWDM is therefore a practical, cost-efficient solution for expanding network capacity in access and metro networks, while DWDM is preferred for high-capacity, long-distance backbone networks.
