Can fiber optic patch cords be made into pigtails

Overview

Fiber Optic Pigtails: Uses & Differences from Patch CordsIn this guide, we will break down what fiber optic pigtails are, how they differ from patch cords.

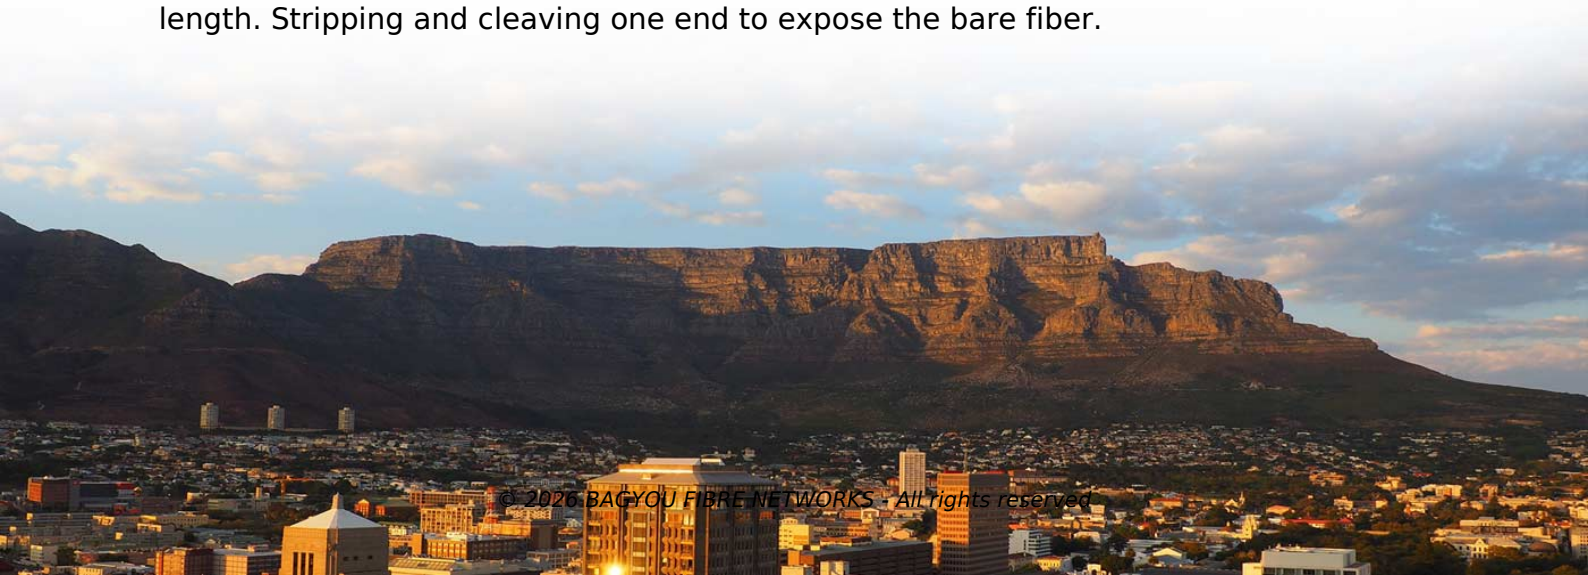

Key Takeaways

Yes, fiber optic patch cords can be made into pigtails by cutting the cord to create a bare fiber end for splicing.

Key Differences Between Patch Cords and Pigtails

A fiber optic patch cord has connectors on both ends and is designed for plug-and-play connections between devices or patch panels, providing flexibility and easy maintenance. In contrast, a fiber optic pigtail has a factory-terminated connector on one end and a bare fiber on the other, intended for permanent fusion or mechanical splicing to a bulk fiber cable. This structural difference is crucial for network deployment, as pigtails act as a bridge between backbone cables and equipment.

Converting Patch Cords into PigtailsIt is technically possible to cut a patch cord in half to produce two pigtails. The process involves: Cutting the patch cord to the desired length. Stripping and cleaving one end to expose the bare fiber.

Preparing the bare fiber for fusion or mechanical splicing to the backbone or multi-core fiber cable. This method allows the use of pre-terminated connectors from the patch cord while creating a splicable end for permanent installation. However, it is important to note that testing the bare fiber end before splicing is challenging, and the resulting pigtail may not match the performance of a factory-manufactured pigtail in terms of insertion loss and return loss.

Practical Considerations

Fiber Type Compatibility: Ensure the patch cord fiber type (single-mode or multimode) matches the backbone cable to avoid signal degradation. Connector Type: The connector on the patch cord should match the equipment or patch panel requirements. Splicing Method: Fusion splicing is preferred for low-loss, long-term stability, while mechanical splicing can be used for temporary or quick installations.

Length and Jacket Size: Pigtails are typically 0. 5–2 meters long with thin jackets to fit in splice trays, so the cut patch cord should be trimmed accordingly.

Conclusion

While factory-made pigtails are generally recommended for optimal performance, patch cords can be converted into pigtails in the field by cutting and preparing one end for splicing. This approach can save time and resources, especially in situations where pre-made pigtails are unavailable, but care must be taken to maintain fiber integrity and minimize signal loss.
