

The access switch needs to be configured with VLANs

Overview

Before you create VLANs, you must decide whether to use VLAN Trunking Protocol (VTP) to maintain global VLAN configuration for your network.

Key Takeaways

Yes, access switch ports should be configured with VLANs to ensure proper traffic segregation and network communication. Access Ports and VLANsAn access port is a switch port that carries traffic for a single VLAN and connects end devices such as PCs, printers, or IP phones to the network. By default, all switch ports belong to VLAN 1, which is the default VLAN on most switches.

If you do not explicitly assign a VLAN to an access port, it will carry traffic for VLAN 1. While this allows basic connectivity, it does not provide network segmentation or security between different groups of devices.

Why Configure VLA

Ns on Access PortsTraffic Segregation: Assigning a VLAN to an access port ensures that devices connected to that port are isolated from devices in other VLANs, creating separate broadcast domains. Security: VLANs prevent unauthorized access between different network segments and reduce the risk of VLAN hopping attacks. Network Management: Proper VLAN assignment simplifies troubleshooting, monitoring, and applying policies to specific groups of devices.

How to Configure VLANs To configure an access port on a Cisco switch: Set the port to access mode: `switchport mode access`. Assign the port to a specific VLAN: `switchport access vlan`. It is important to create the VLAN on the switch before assigning it to an access port.

If the VLA

N does not exist, the port may shut down or drop traffic.

Default VLAN Considerations

If you only use the default VLAN (VLAN 1), you technically do not need to configure additional VLANs for basic connectivity. However, for most enterprise networks, creating and assigning VLANs is considered best practice to improve security, scalability, and traffic management.

Summary

While an access port can operate on the default VLAN without explicit configuration, assigning VLANs to access ports is recommended to properly segment the network, enhance security, and manage traffic efficiently.

Without VLA

N configuration, all devices share the same broadcast domain, which can lead to congestion and potential security risks.

Cisco Switchport Mode Access vs Switchport Access VLAN

The switchport access VLAN is a command which assigns layer 2 interface on a Cisco switch to specific VLAN. This command takes effect only if the interface is operating in switchport

Access and Trunk Ports

Access ports are typically configured to carry traffic for a single VLAN, which provides a layer of security by segregating traffic between different VLANs. Access ports are less complex than

How to Create and Configure VLANs on a Cisco Switch with Example

This post will deal with creating Layer 2 VLANs on Cisco switches and performing all relevant configurations. Up to 4094 VLANs can be configured on Cisco catalyst switches.

Configuring VLANs

After creating the VLANs on the switches, it is crucial to assign the correct ports to each VLAN. This assignment ensures that devices are properly grouped, which enhances both
